1 Introduction

Phase-field simulation is a versatile application in the toolbox of materials simulation. It is often used for simulations of phase transitions, dislocation evolution, fracture simulations etc. The following practicals aim is to get a practical introduction into the subject. In two separate tasks a 1D single-component solidification simulation, calculation of a bulk energy density coefficient and gradient energy density coefficient are going to be conducted.

2 Task 1: 1D Single-Component Solidification

To simulate a 1D single-component solidification we utilize the following energy density:

$$F = \int (f_0 \phi^2 (1 - \phi)^2 + \frac{K_\phi}{2} |\nabla \phi|^2) d\vec{r} \quad (1)$$

As solidification is a non-conservative process, the kinetics are governed by the Allen-Cahn equation (for the homogeneous, isotropic case).

$$\frac{\partial \phi}{\partial t} = -L \frac{\delta F}{\delta \phi} \quad (2)$$

Here the functional derivative $\frac{\delta F}{\delta \phi}$ of an energy functional eq. 3a can be evaluated as eq. 3b.

$$F = \int f(\vec{r}, \phi, \nabla \phi) d\vec{r} \quad (3a)$$

$$\frac{\delta F}{\delta \phi} = \frac{\partial f}{\partial \phi} - \nabla \cdot \frac{\partial f}{\partial (\nabla \phi)} \quad (3b)$$

Solving the functional derivative from eq. 2 yields:

$$\frac{\delta F}{\delta \phi} = 2f_0 \phi (1 - \phi)^2 + 2f_0 \phi^2 (\phi - 1) - K_\phi \nabla^2 \phi \Leftrightarrow \quad (4a)$$

$$\Leftrightarrow 2\phi^3 - 4\phi^2 + 2\phi \quad (4b)$$

Inserting the result into eq. 2 results in:

$$\frac{\partial \phi}{\partial t} = -L[f_0(2\phi^3 - 4\phi^2 + 2\phi) - K_\phi \nabla^2 \phi] \quad (5)$$

As the governing equation for solving the PDE we apply Dirichlet boundary conditions $\phi_1 = 0; \phi_n = 1$ and discretize the partial derivative $\frac{\partial \phi}{\partial t}$ as:

$$\frac{\partial \phi}{\partial t} \approx \frac{\phi_{next} - \phi}{\Delta t} = -L[f_0(2\phi^3 - 4\phi^2 + 2\phi) - K_\phi \nabla^2 \phi] \Leftrightarrow \quad (6a)$$

$$\Leftrightarrow \phi_{next} = -\Delta t L[f_0(2\phi^3 - 4\phi^2 + 2\phi) - K_\phi \nabla^2 \phi] \quad (6b)$$

and $\nabla^2 \phi(x)$ is discretized according to the (forward) finite differences scheme:

$$\nabla^2 \phi(x_i) \approx \frac{\phi(x_{i+2}) - 2\phi(x_{i+1}) + \phi(x_i)}{\Delta x} \quad (7)$$

where x_i is the node at which the value is computed and Δx is the node distance. The initial result is plotted in fig. 2. As can be seen in 2 f_0 seems to be reciprocally proportional energy functional over time. With decreasing value the transition region (where ϕ changes from 0 to 1) becomes broader. The opposite effect can be observed in fig. 2 with variation of K_ϕ . Additional the energy density functional seems to become broader but only changes its peak value for increased K-values. L does not seem to have any influence on the ϕ , the energy or energy density - see fig. 2 .

Figure 2: Results of the 1D single-component solidification simulation with various f_0 values.

Figure 3: Results of the 1D single-component solidification simulation with various K values.

Figure 4: Results of the 1D single-component solidification simulation with various L values.

3 Task 2

The equilibrium Al concentration of the disordered γ -Phase c_γ^e has been determined to be 0.165 and the Al concentration of the ordered γ' -Phase $c_{\gamma'}^e$ has been determined to be 0.230 [1]. The bulk energy density function is constructed as:

$$f_{bulk} = f_0(c_{\gamma'}^e - c)^2(c_\gamma^e - c)^2 \quad (8)$$

The f_0 needs to be fitted so that it results in an energy gradient of $\Delta f 149 \frac{\text{J}}{\text{mol}}$ [2]. This is accomplished by choosing the right f_0 to reach the right value at the local maximum of eq. 8. The local maximum of the function can be found automatically by finding the second root of the derivative of eq. 8:

$$\frac{df_{bulk}}{dc} = -2f_0(c_{\gamma'}^e - c)(c - c_\gamma^e)^2 + 2f_0(c_{\gamma'}^e - c)^2(c - c_\gamma^e) \quad (9)$$

Using the `scipy` package of Python this can be achieved using `scipy.optimize.root_scalar(func, x0=0.2)` where 0.2 is the initial starting point, looking for c_{max} . Here c_{max} is found at 0.1975. Solving 8 for f_0 results in a value of $\approx 133.6 \cdot 10^6 \frac{\text{J}}{\text{mol}}$. The resulting function of the corresponding parameters is plotted in 3.

Figure 5: Calculated chemical free energy as a function of composition for both the disordered and ordered phase at 1300 K reproduced from [1].

Figure 6: Plot of bulk energy of binary NiAl mixture with $c_{\gamma}^e = 0.165$, $c_{\gamma'}^e = 0.23$ and $f_0 = 133.6 \cdot 10^6 \frac{\text{J}}{\text{mol}}$
